

Real-time small-size space debris detection with Eiscat
radar facilities

INTRODUCTION

Study objectives

- Based on developments of the precursor study,
- Develop methods to perform real-time detection of small-sized space debris objects in LEO during routine Eiscat operations,
- Demonstrate real-time detection during standard Eiscat experiment campaigns.

Debris

L ($> 10\text{cm}$) ~ 11000 Tracked
by US SSN

“The dots represent the current location of each item. The orbital debris dots are scaled according to the image size of the graphic and are not scaled to Earth.”

M ($> 1\text{cm}$)

~ 200000

Sampled
by
radars

S Measured in
situ

Precursor study

- SGO, 2000-2001, lead by M Lehtinen.
- Matlab-based SW implements GMF method.
- Both detection and analysis done off-line.
- 4.1 h of analysed cp1 It, tau2 UHF data: 56 events.
 - “Piggy-backing” SD on Eiscat OK.
 - Sensitivity “2cm at 1000 km range”, but ...
- Coherent integration’s efficiency unknown. Etc.

Present study

- Eiscat, 2002-2003, lead by M Postila.
- c- and Matlab-based SW implements MF method.
- Detection on-line. Analysis on-line or off-line.
- Two copies of measurement HW.

Present study (cont'd)

- 157 h of analysed UHF data: 2560 events.
 - Piggy-backing SD on Eiscat routinely OK.
 - Sensitivity “2 cm at 1000 km range”, but ...
- Coherent integration's efficiency unknown. Etc.

WP structure of the study

- Updating of the data processing methods and algorithms.
- Real-time detection and parameter estimation of space debris echos in raw data acquired during the precursor study.
- Real-time detection during routine operations of one selected Eiscat radar facility.
- Investigation of the Possibilities of Orbital Parameter Determination with the Eiscat radars.

Structure of this talk

- Introduction
- Hardware
- Measurement theory
- Software
- Measurement results
- Summary

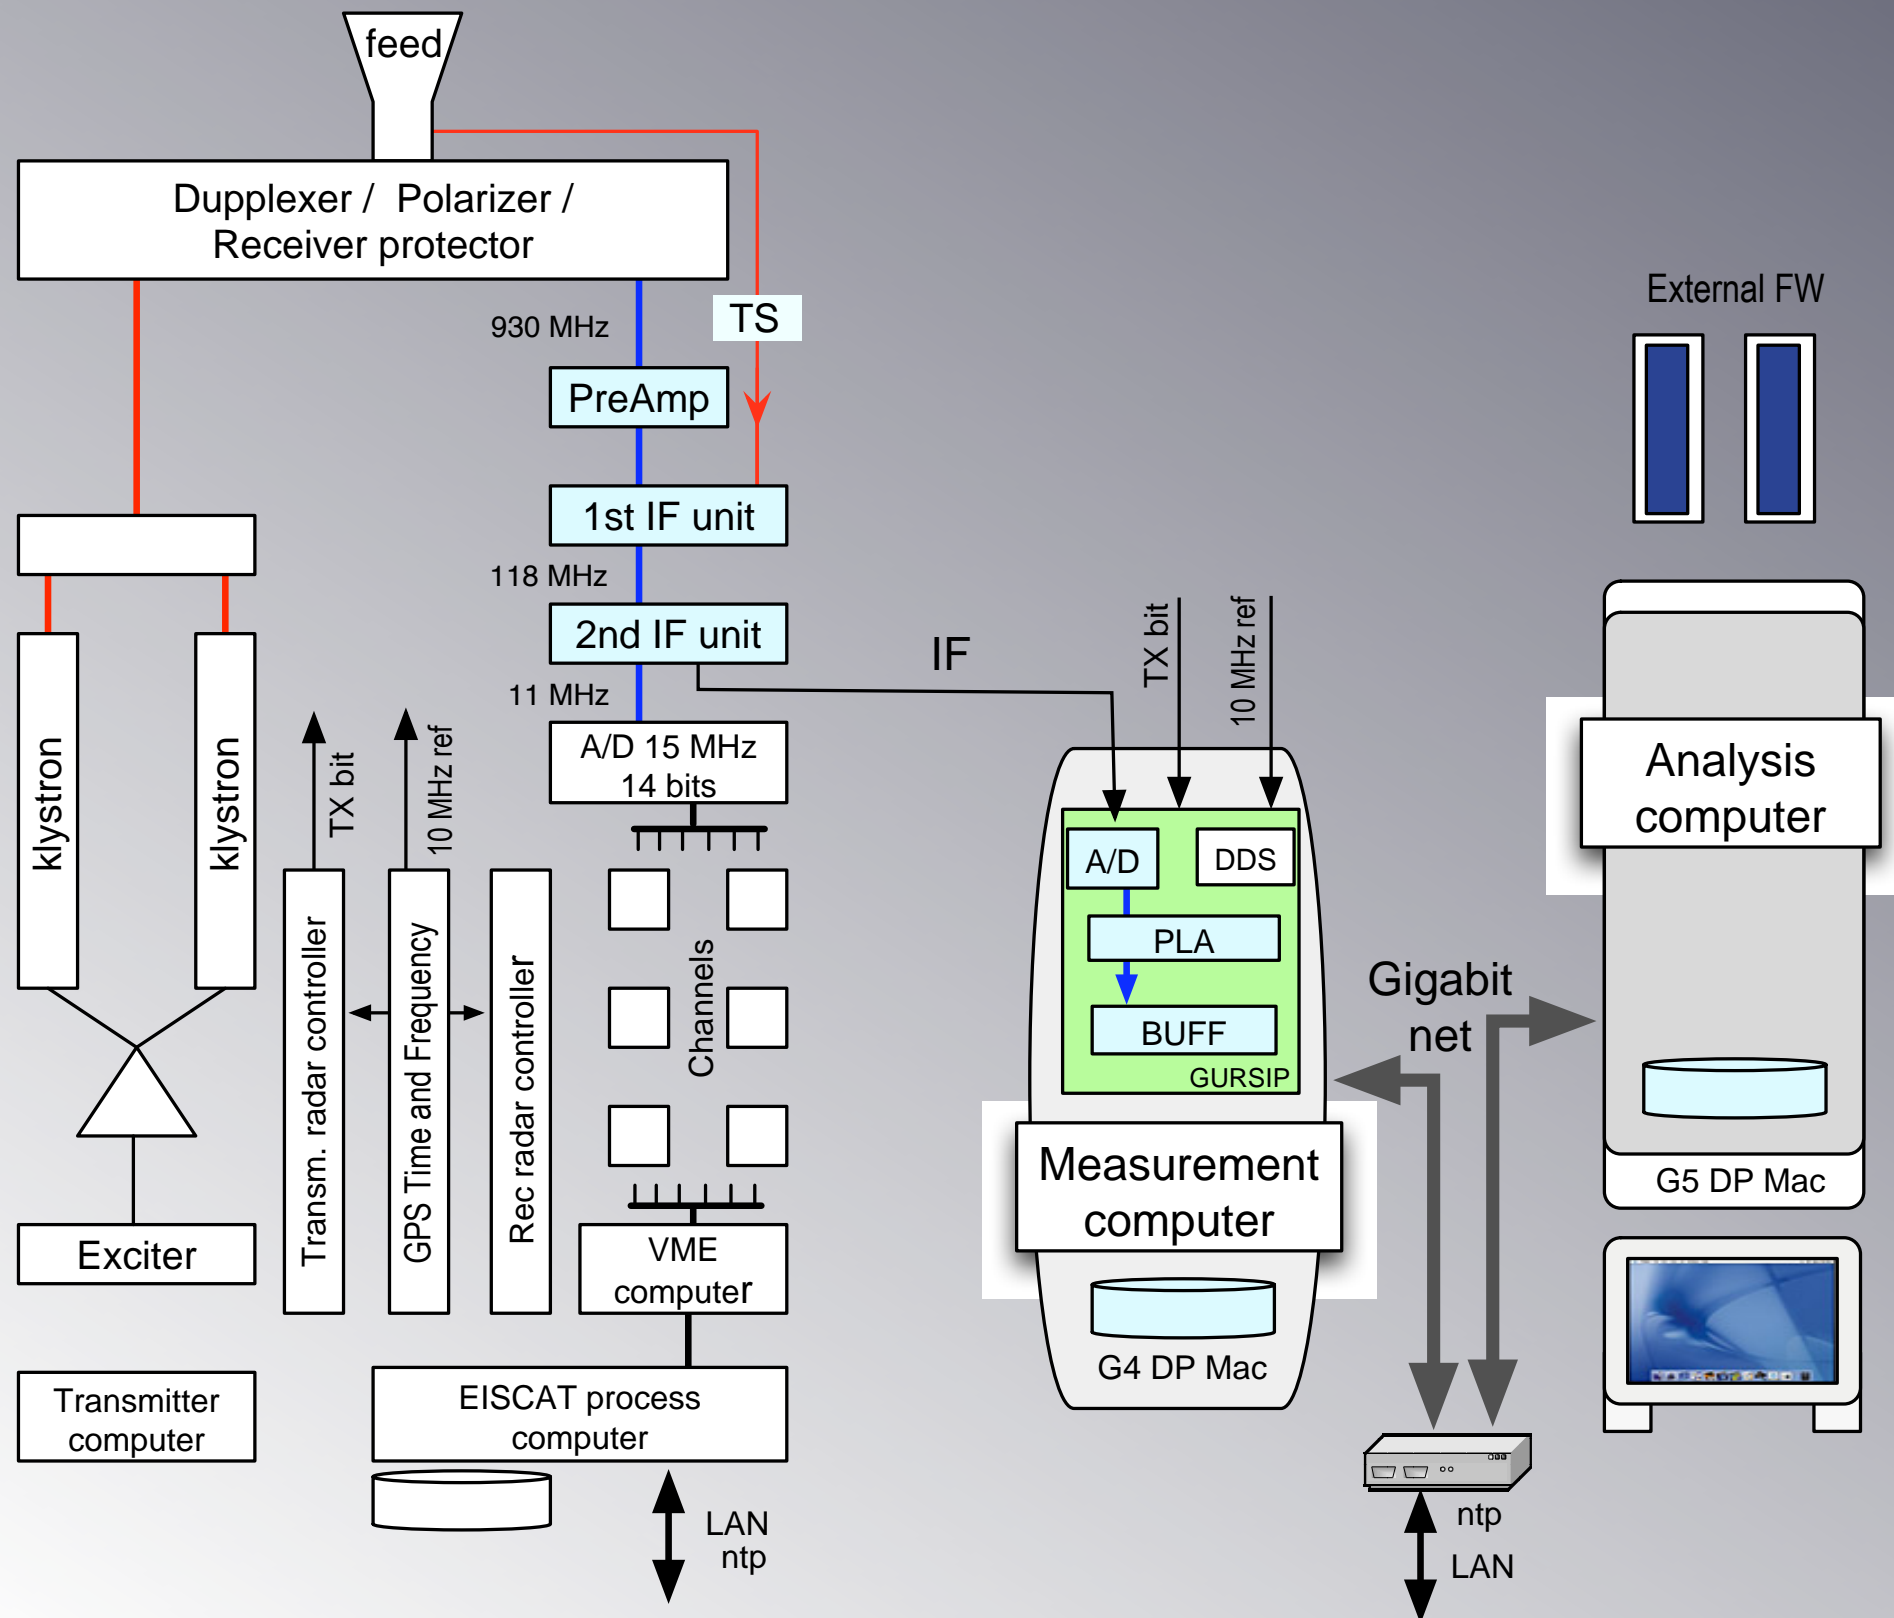

Real-time small-size space debris detection with Eiscat
radar facilities

THEORY

Measurement theory

Requested:

$$R, v_r, a_r, W_s$$

Received signal is

$$z(t) = s(t) + \gamma(t)$$

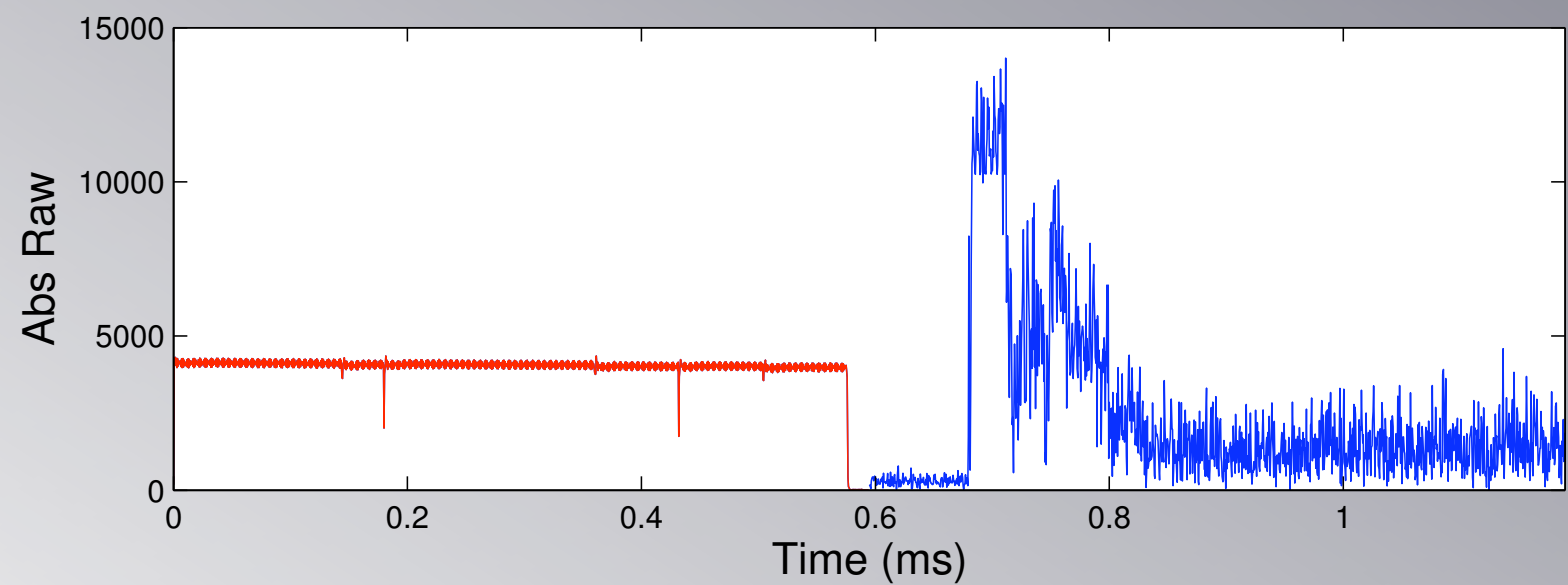

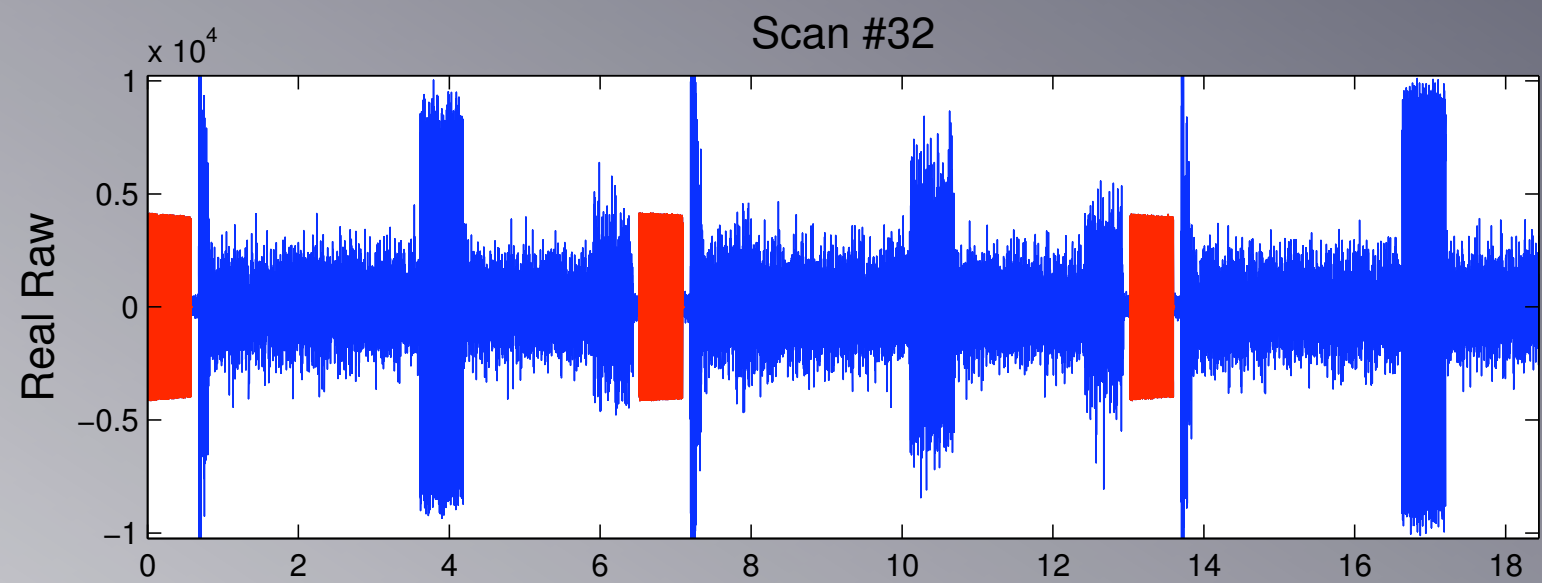

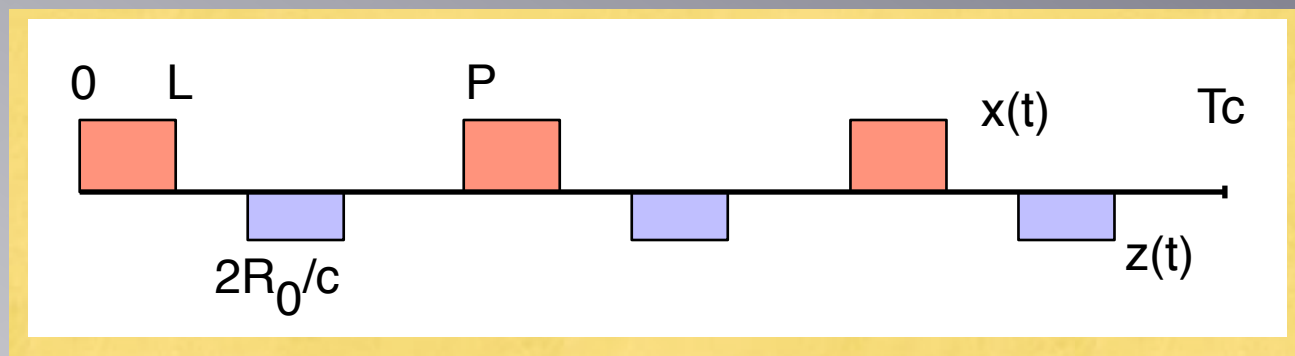

$$s(t) = b \cdot \chi(\theta; t)$$

Available: sample vector

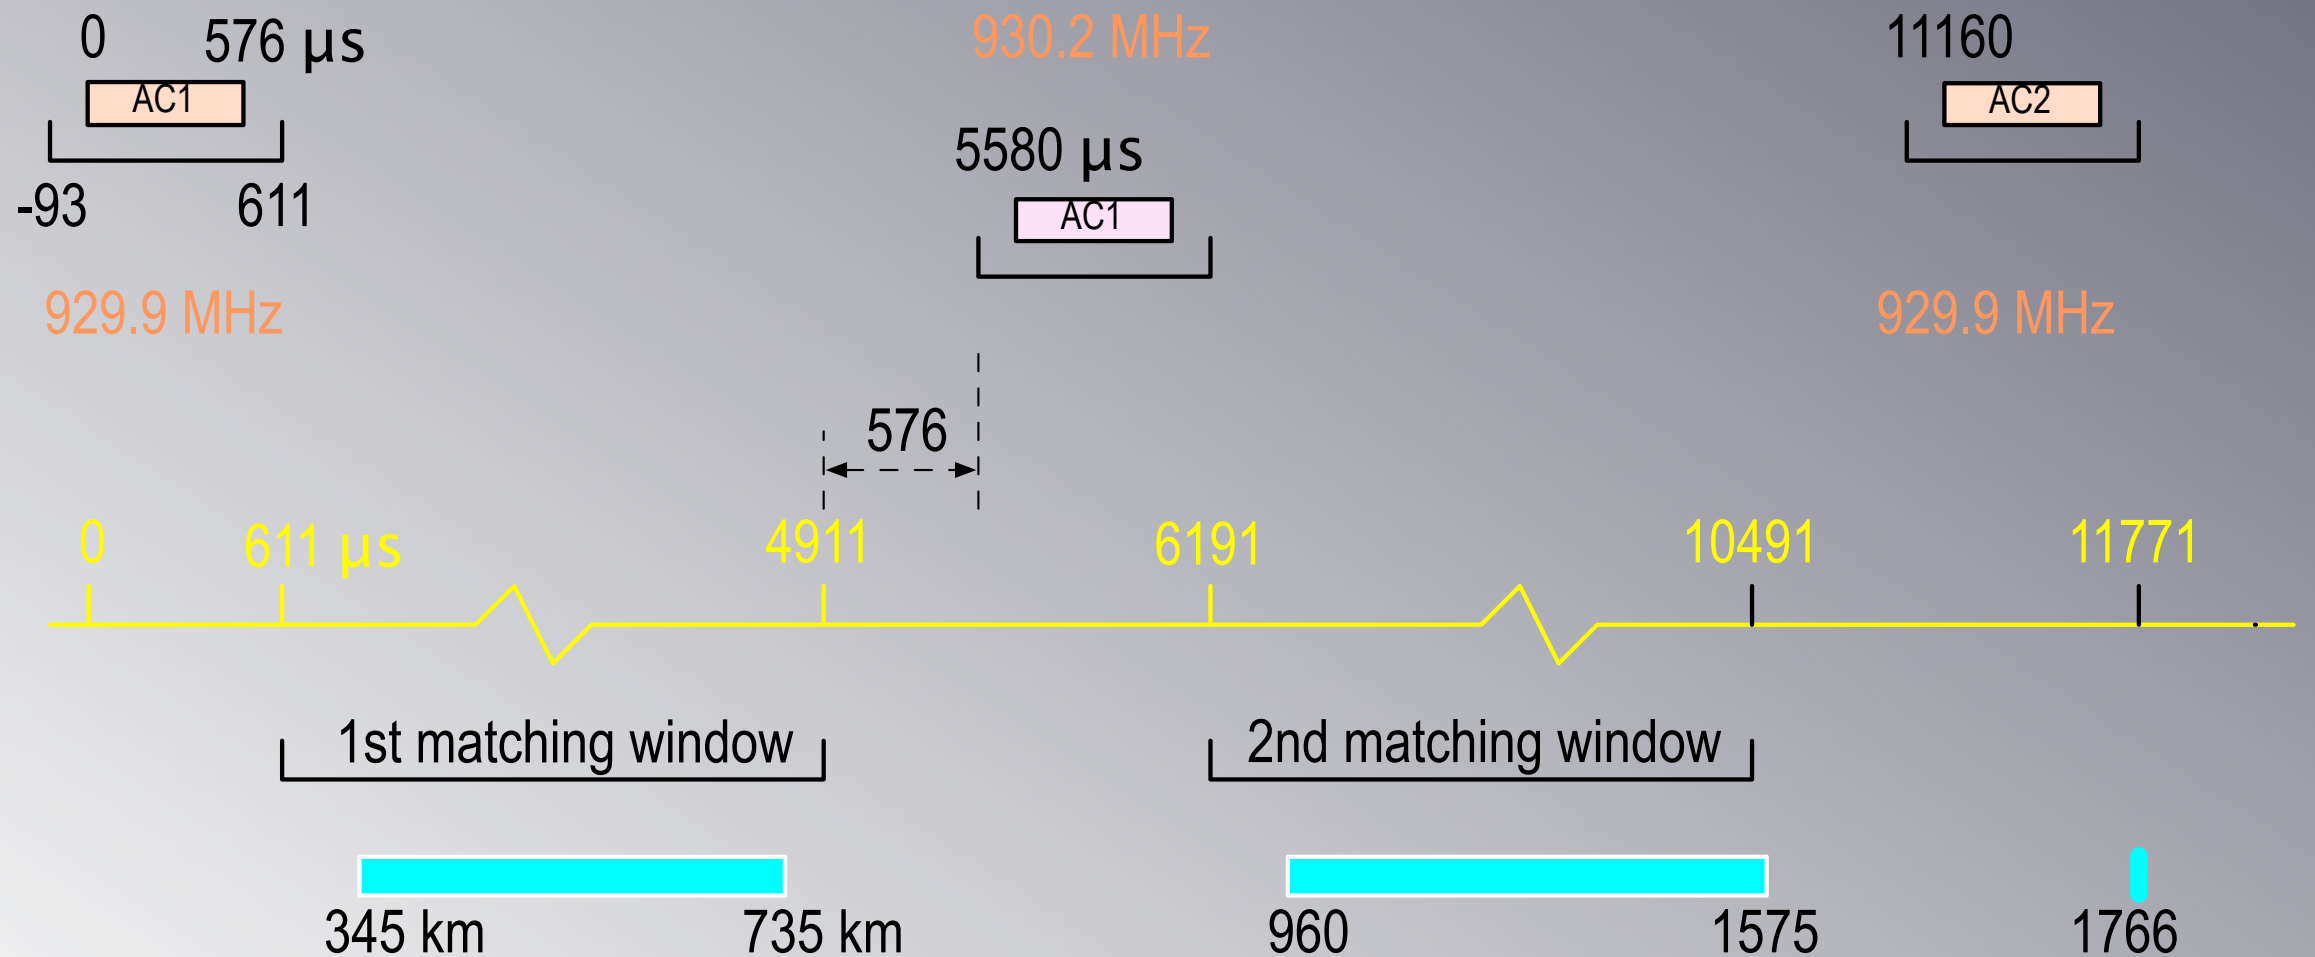

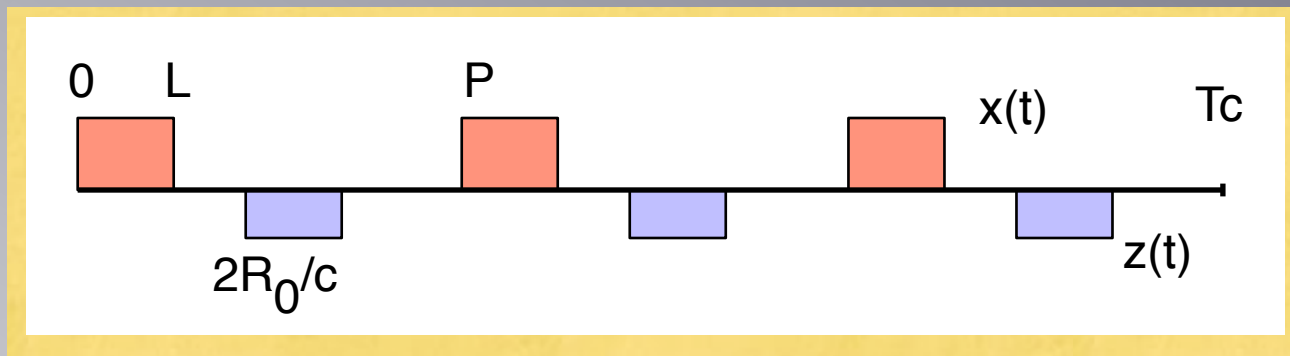

$$z_n = z(n \cdot \tau_s), n = \dots 10^5$$

Raw data

Tau2 transmission

Inversion solution

Posteriori density (with constant prior)

$$D_p(b, \theta | z) = C(z) \cdot e^{-\frac{1}{\sigma^2} \|z - b \cdot \chi(\theta)\|^2}$$

Bayesian parameter estimate

$$(\hat{b}, \hat{\theta}) = \arg \max_{b, \theta} D_p(b, \theta | z)$$

In practice

Define *match function*

$$\text{MF}(\theta) = \frac{|\langle z, \chi(\theta) \rangle|}{\|\chi(\theta)\|}$$

Then

$$\hat{\theta} = \arg \max_{\theta} \text{MF}(\theta)$$

$$\hat{s} = \frac{\langle z, \hat{\chi} \rangle}{\|\hat{\chi}\|^2} \hat{\chi}$$

$$\text{where } \hat{\chi} = \chi(\hat{\theta})$$

The work goes here

Signal energy estimate

For correctly sampled voltages $x(t)$, energy is

$$W_x = \int |x(t)|^2 dt \approx \tau_s \sum |x_n|^2 = \tau_s \|x\|^2$$

Use

$$\widehat{W}_s = W_s$$

Then

$$\widehat{\text{SNR}}_N \equiv \frac{\widehat{W}_s}{kT_{\text{sys}}} \approx \frac{\max \text{MF}^2}{\sigma^2}$$

Target detection

Detection criterion

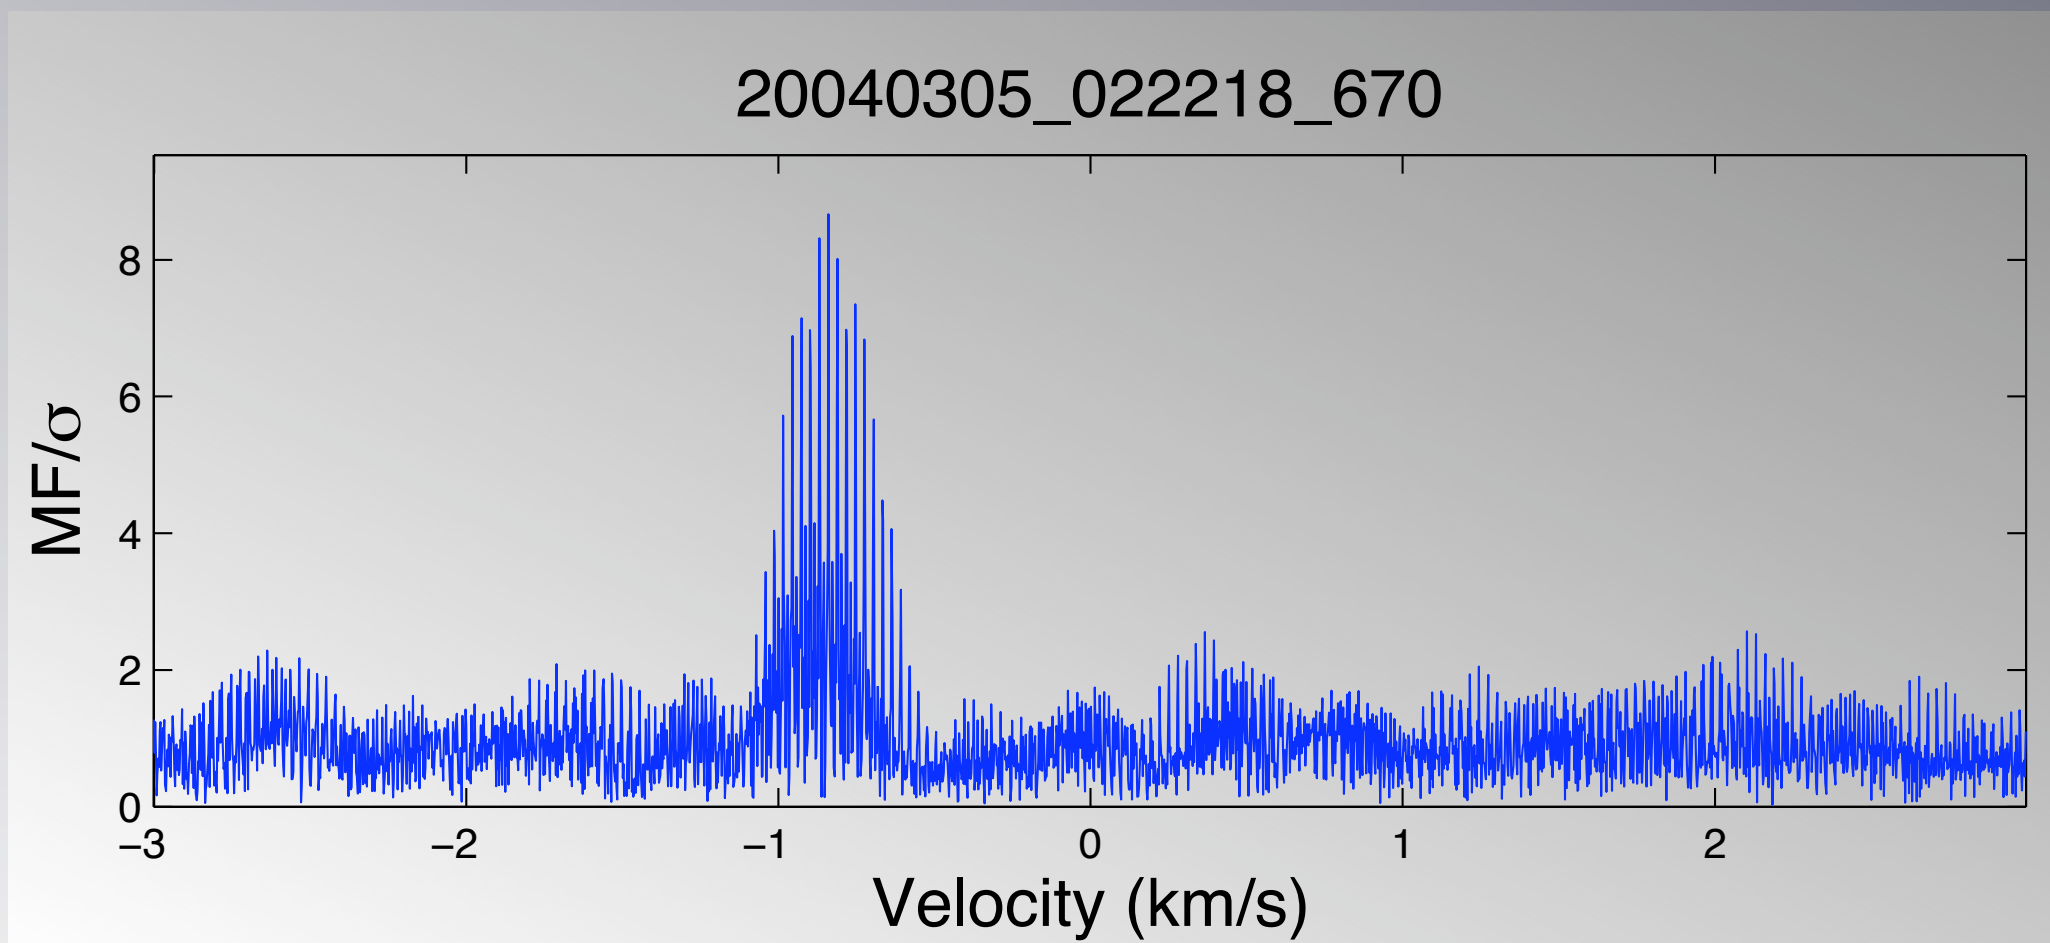

$$\sqrt{\widehat{\text{SNR}}_N} = \frac{\max \text{MF}}{\sigma} > \text{Threshold}$$

Note! Without signal, with typical data,

$$\left\langle \frac{\max \text{MF}}{\sigma} \right\rangle \approx 3$$

Structure of MF(R,v)

$$\max \frac{\text{MF}(R, v)}{\sigma} = \frac{\|\hat{s}\|}{\sigma}$$

Signal model $\chi(t)$

reception \propto delayed transmission

$$s(t) = b \chi(t) = b x(t')$$

$$t - t' = \frac{2r\left(\frac{t'+t}{2}\right)}{c}$$

$$t - t' = \frac{2c}{a_0} \left\{ 1 + \frac{v_0}{c} + \frac{a_0}{c} t - \left[1 + \frac{2v_0}{c} + \left(\frac{v_0}{c}\right)^2 + \frac{2a_0}{c} \left(t - \frac{R_0}{c}\right) \right]^{\frac{1}{2}} \right\}$$

Approx. signal model

$$\chi(R, v, a; t) \approx x\left(t - \frac{2}{c} r\left(R, v, a; t - \frac{R}{c}\right)\right)$$

OK

$$\approx x\left(t - \frac{2R}{c}\right) e^{i(\omega_D t + \alpha_D t^2)}$$

?

$$\omega_D = -\omega_1 \frac{2v}{c}$$

$$\alpha_D = -\omega_1 \frac{a}{c}$$

Discretize

At the points

$$R_j = j \cdot \frac{c\tau_s}{2}$$

$$v_k = k \frac{c}{\omega_1 T_c}$$

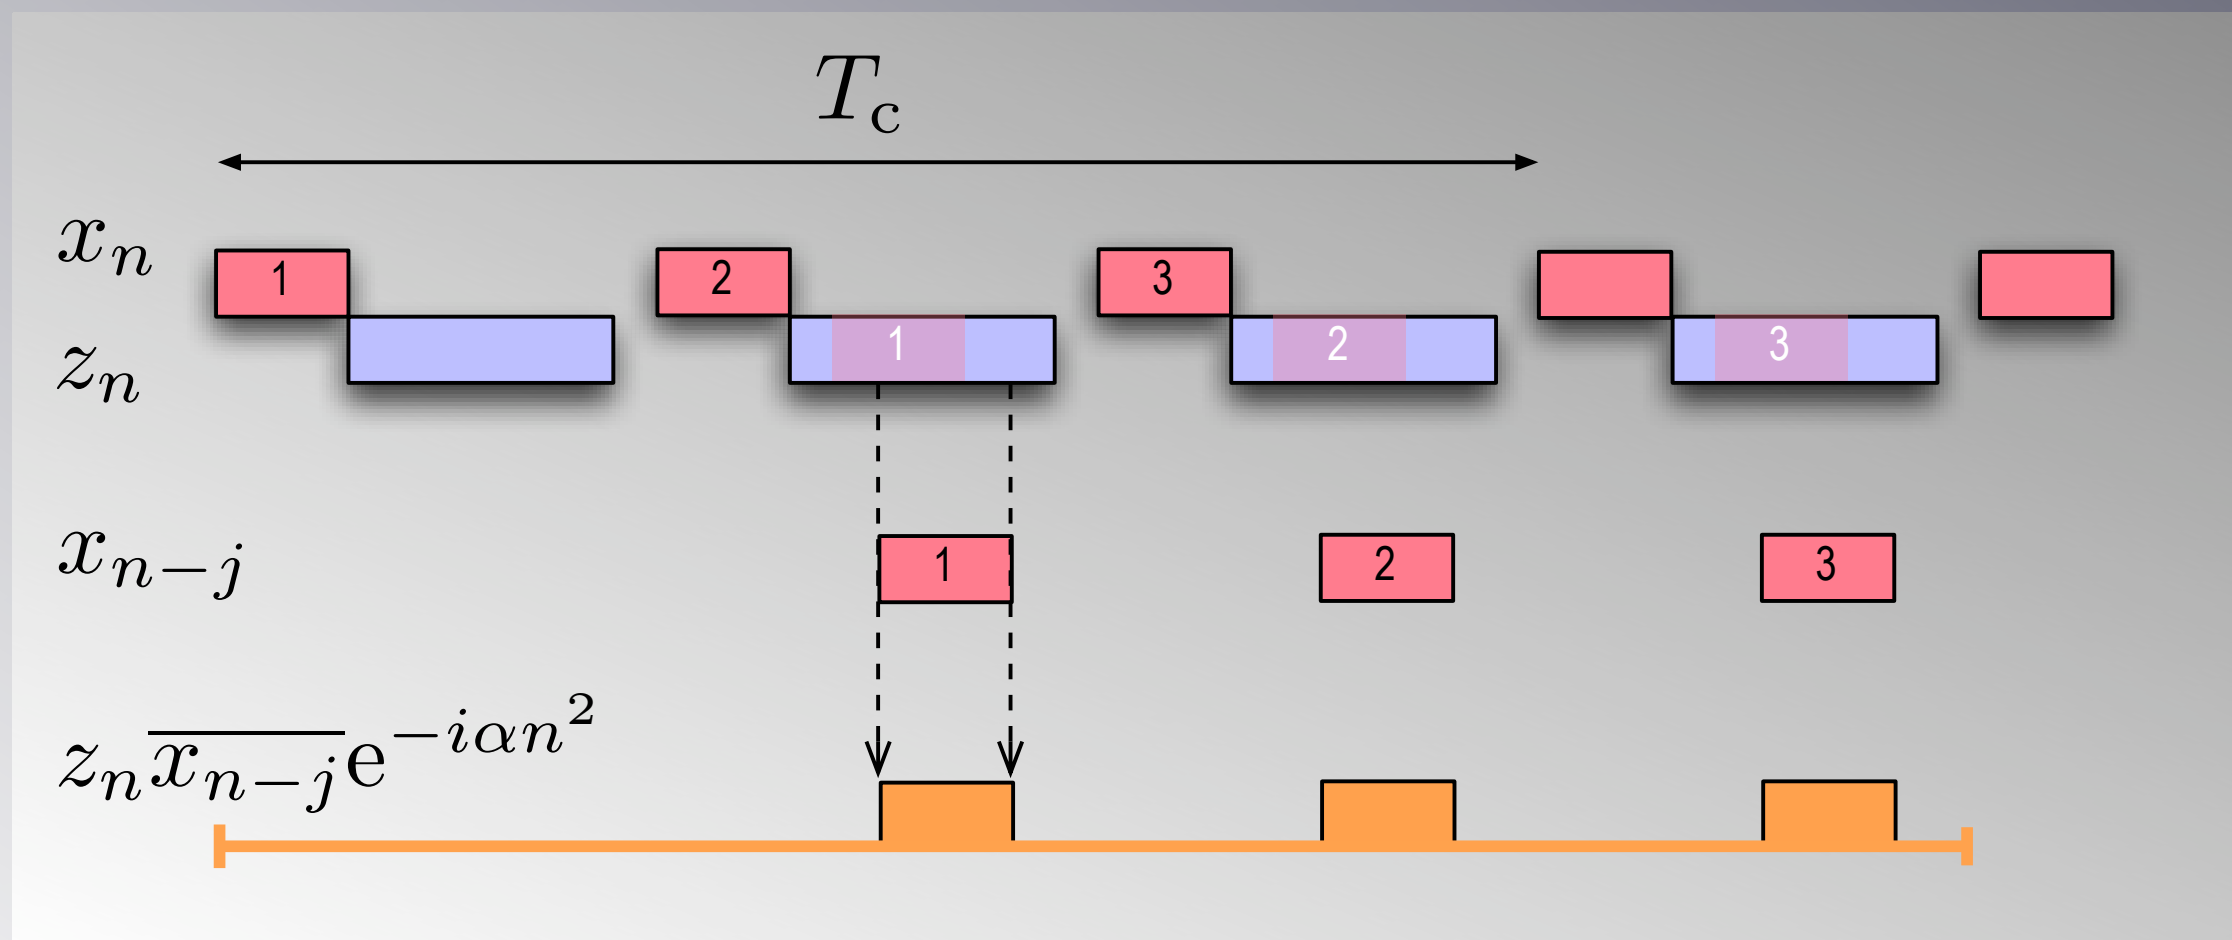

the match function becomes

$$\text{MF}(R_j, v_k, a) = \frac{\left| \sum_{n=0}^{N-1} (z_n \bar{x}_{n-j} e^{-i\alpha_d n^2}) e^{-i\frac{kn}{N}} \right|}{\|x\|}$$

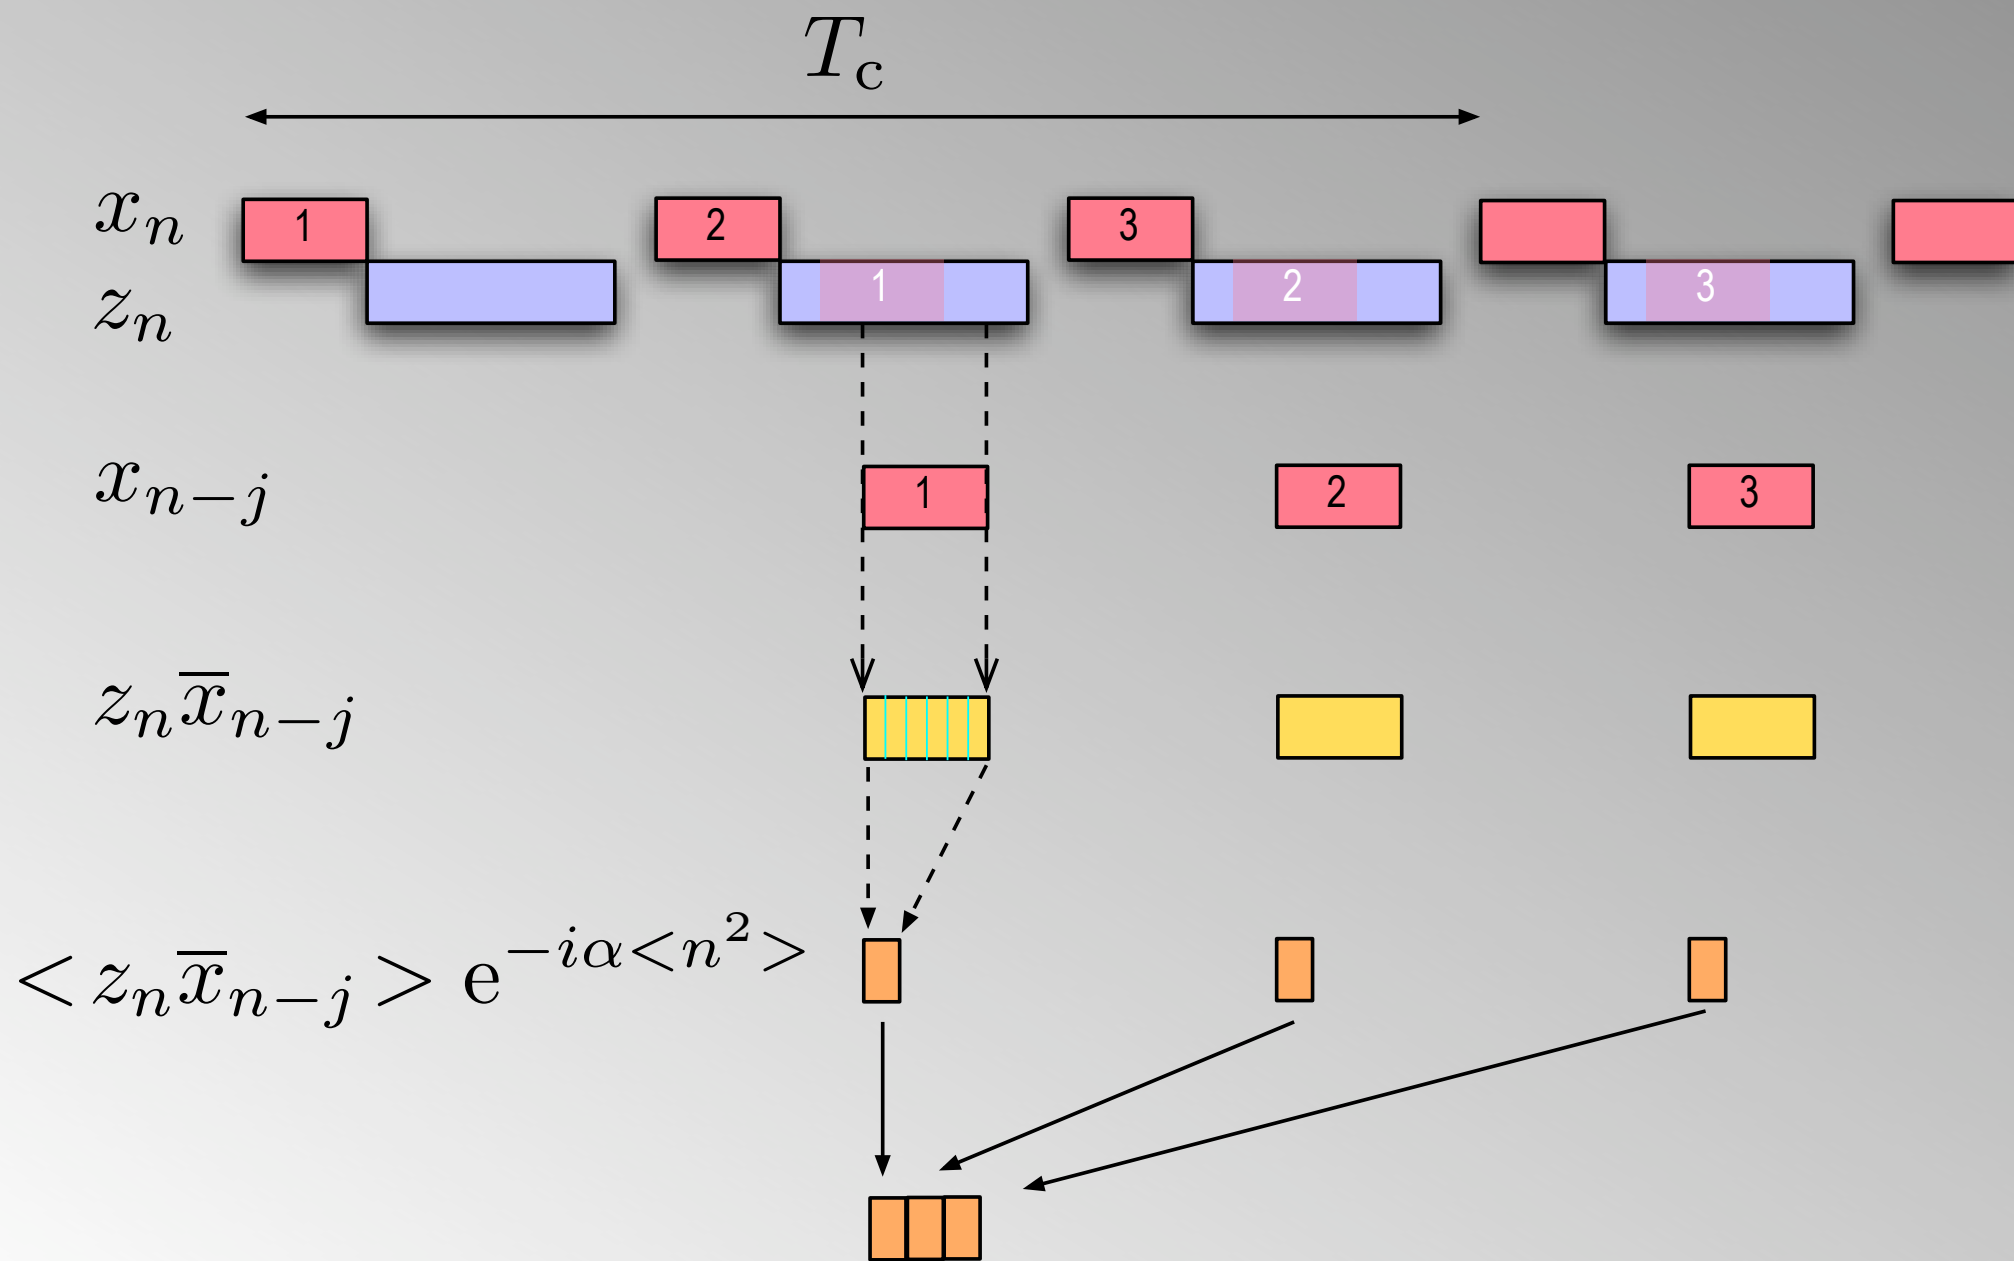

$$\alpha_d = -\omega_1 \tau_s \frac{a\tau_s}{c}$$

The MF algorithm

$$\left| \sum_{n=0}^{N-1} (z_n \bar{x}_{n-j} e^{-i\alpha_d n^2}) e^{-i\frac{kn}{N}} \right|$$

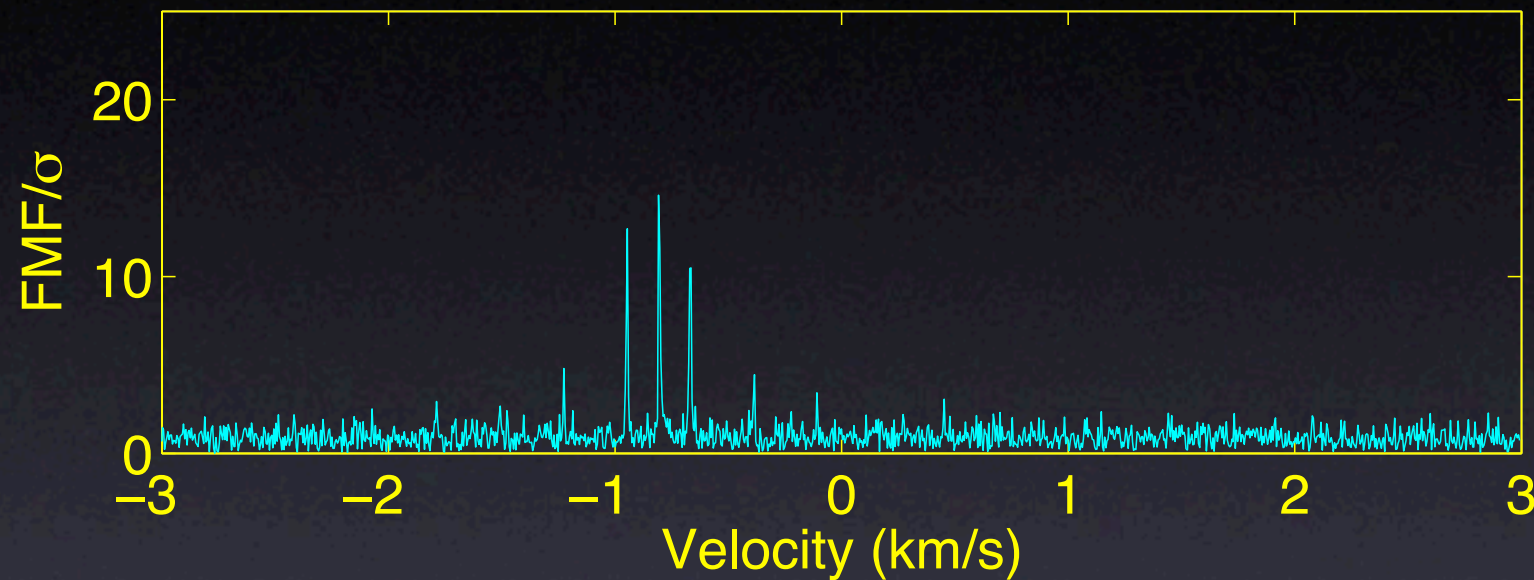

The FMMF algorithm

FMF vs MF in detection

20040305_022219_072

FMF

1800 Mflops /s
0.26 ms/range gate
max = 14.6
R = 1006.5 km
v = 0.802 km/s

MF

570 Mflops /s
44.9 ms/range gate
max = 22.2
R = 1006.5 km
v = 0.791 km/s

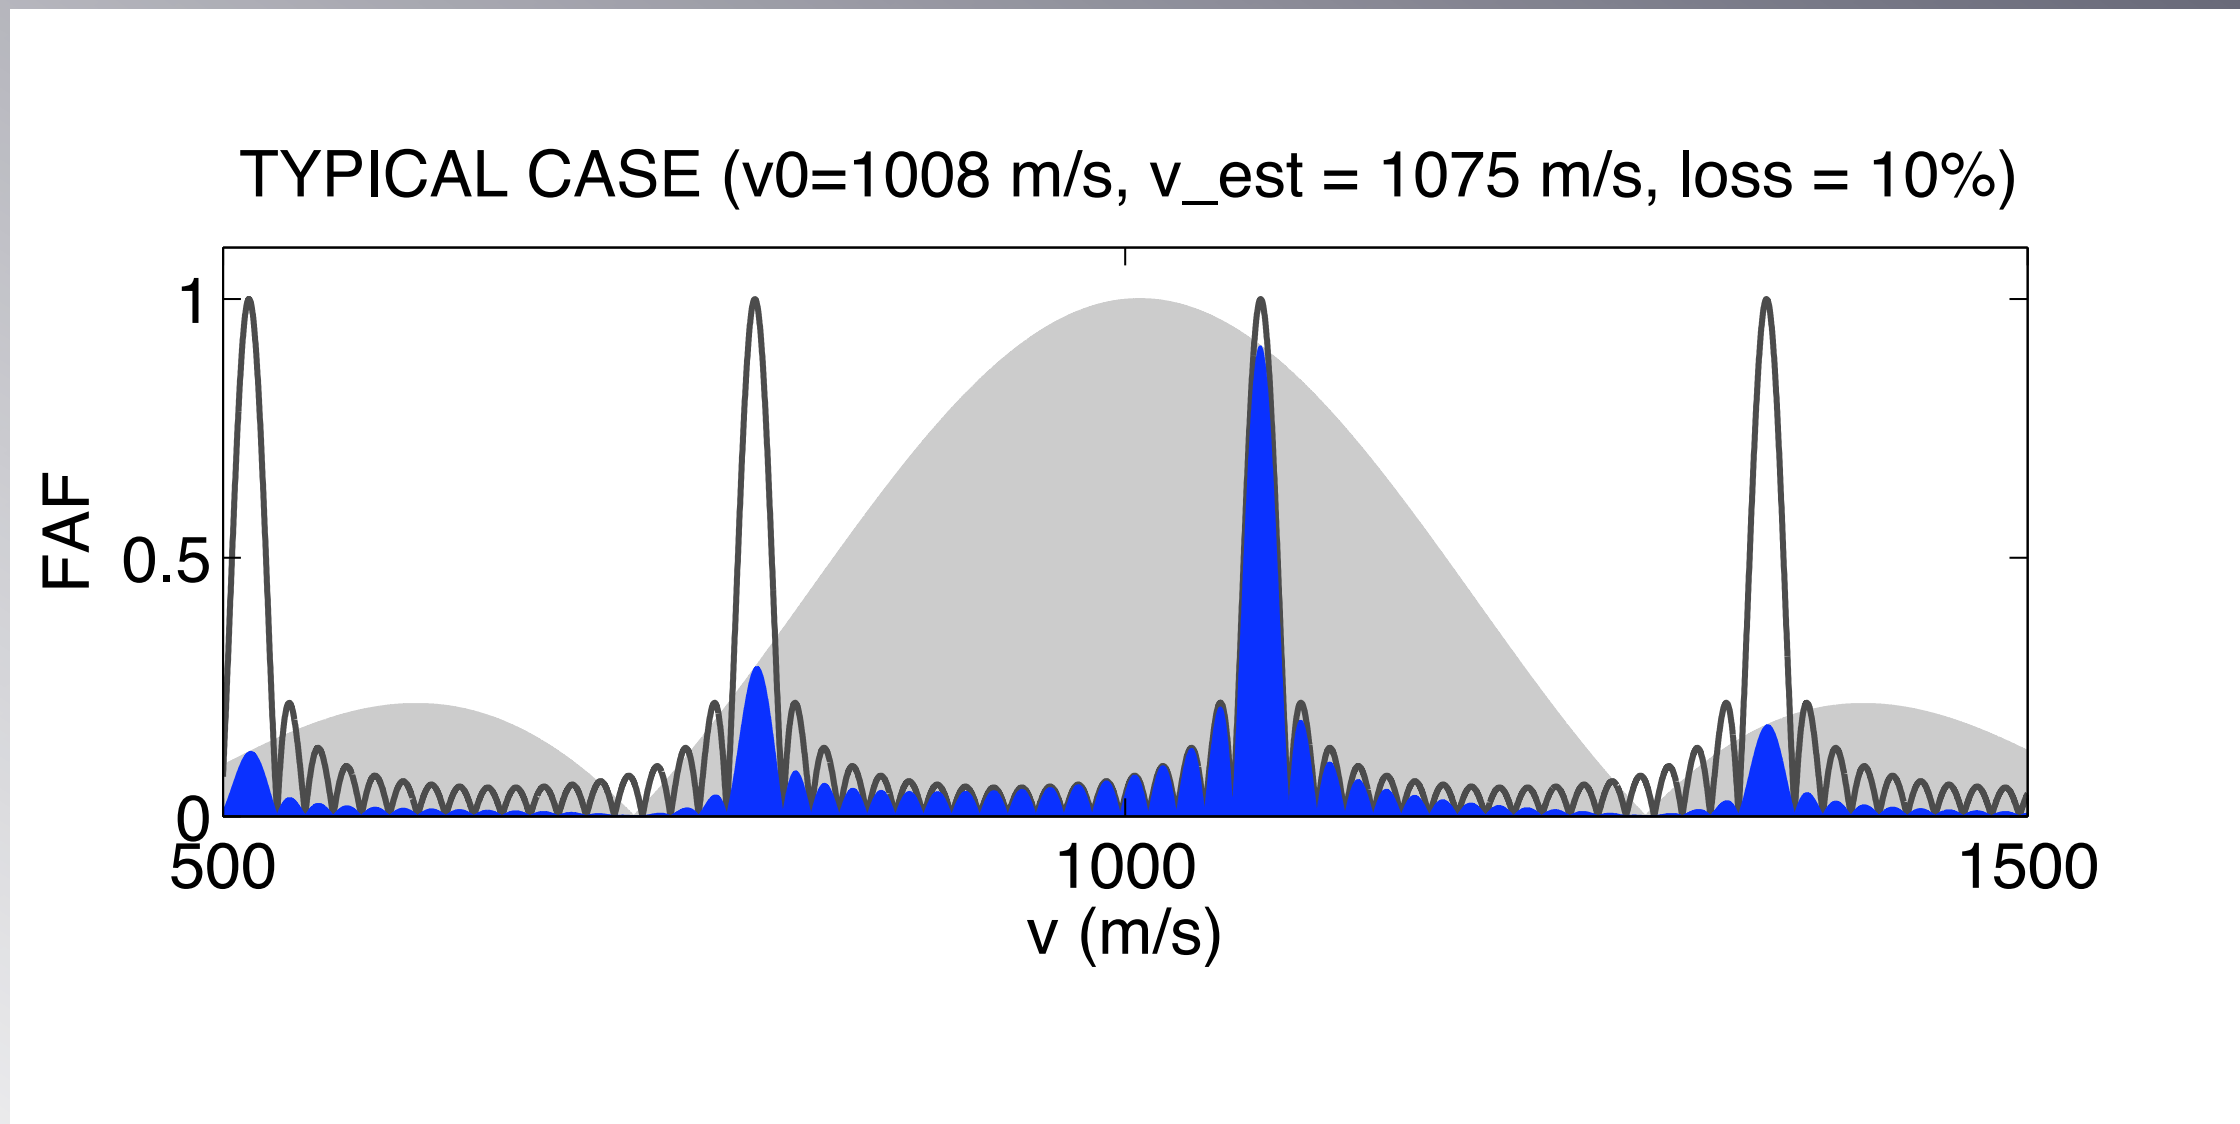

Properties of MF and FMF

- Structure of AF and FAF
- Velocity ambiguities, velocity “jumps”
- Lower bound of FFMF/MF
- Effect of acceleration error
- Dual-frequency case

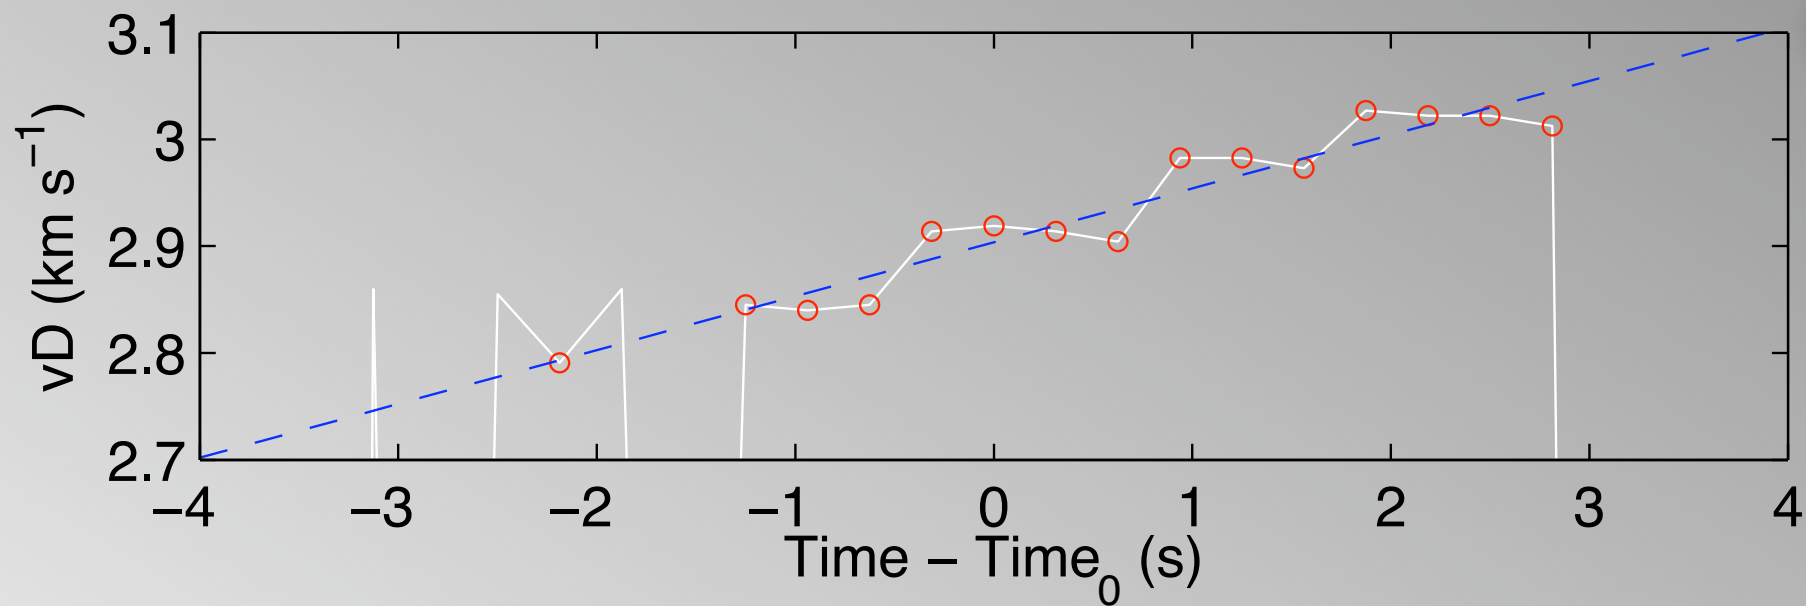

Structure of $AF(R_0, v)$

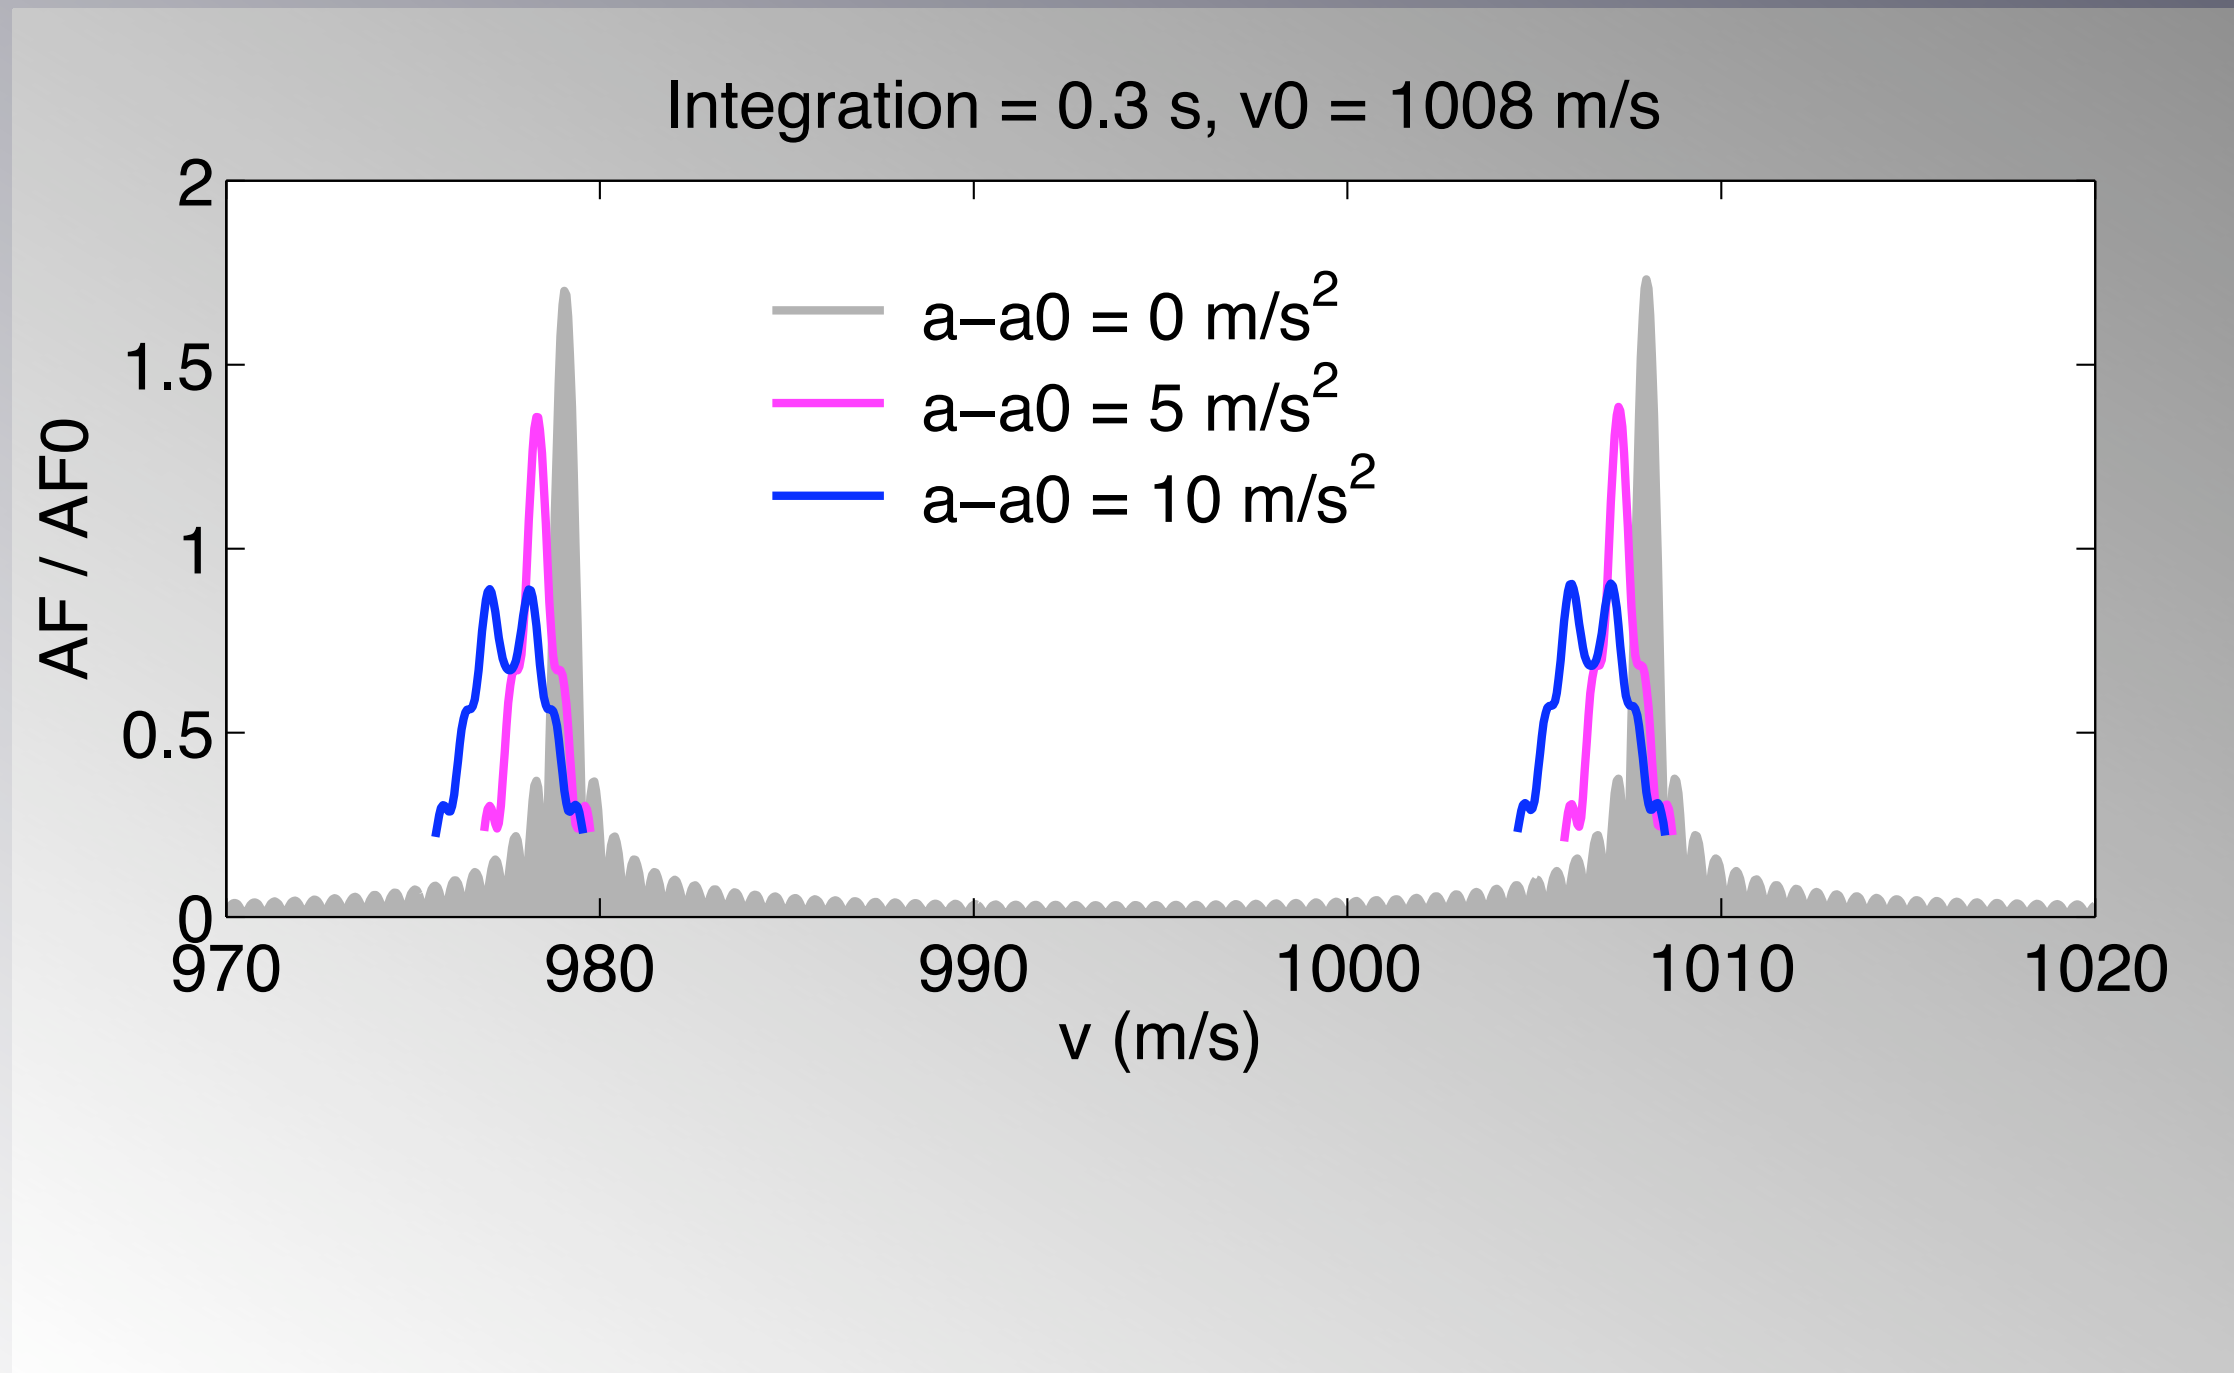

Structure of 1-freq FAF(R_0, v)

Velocity jumps

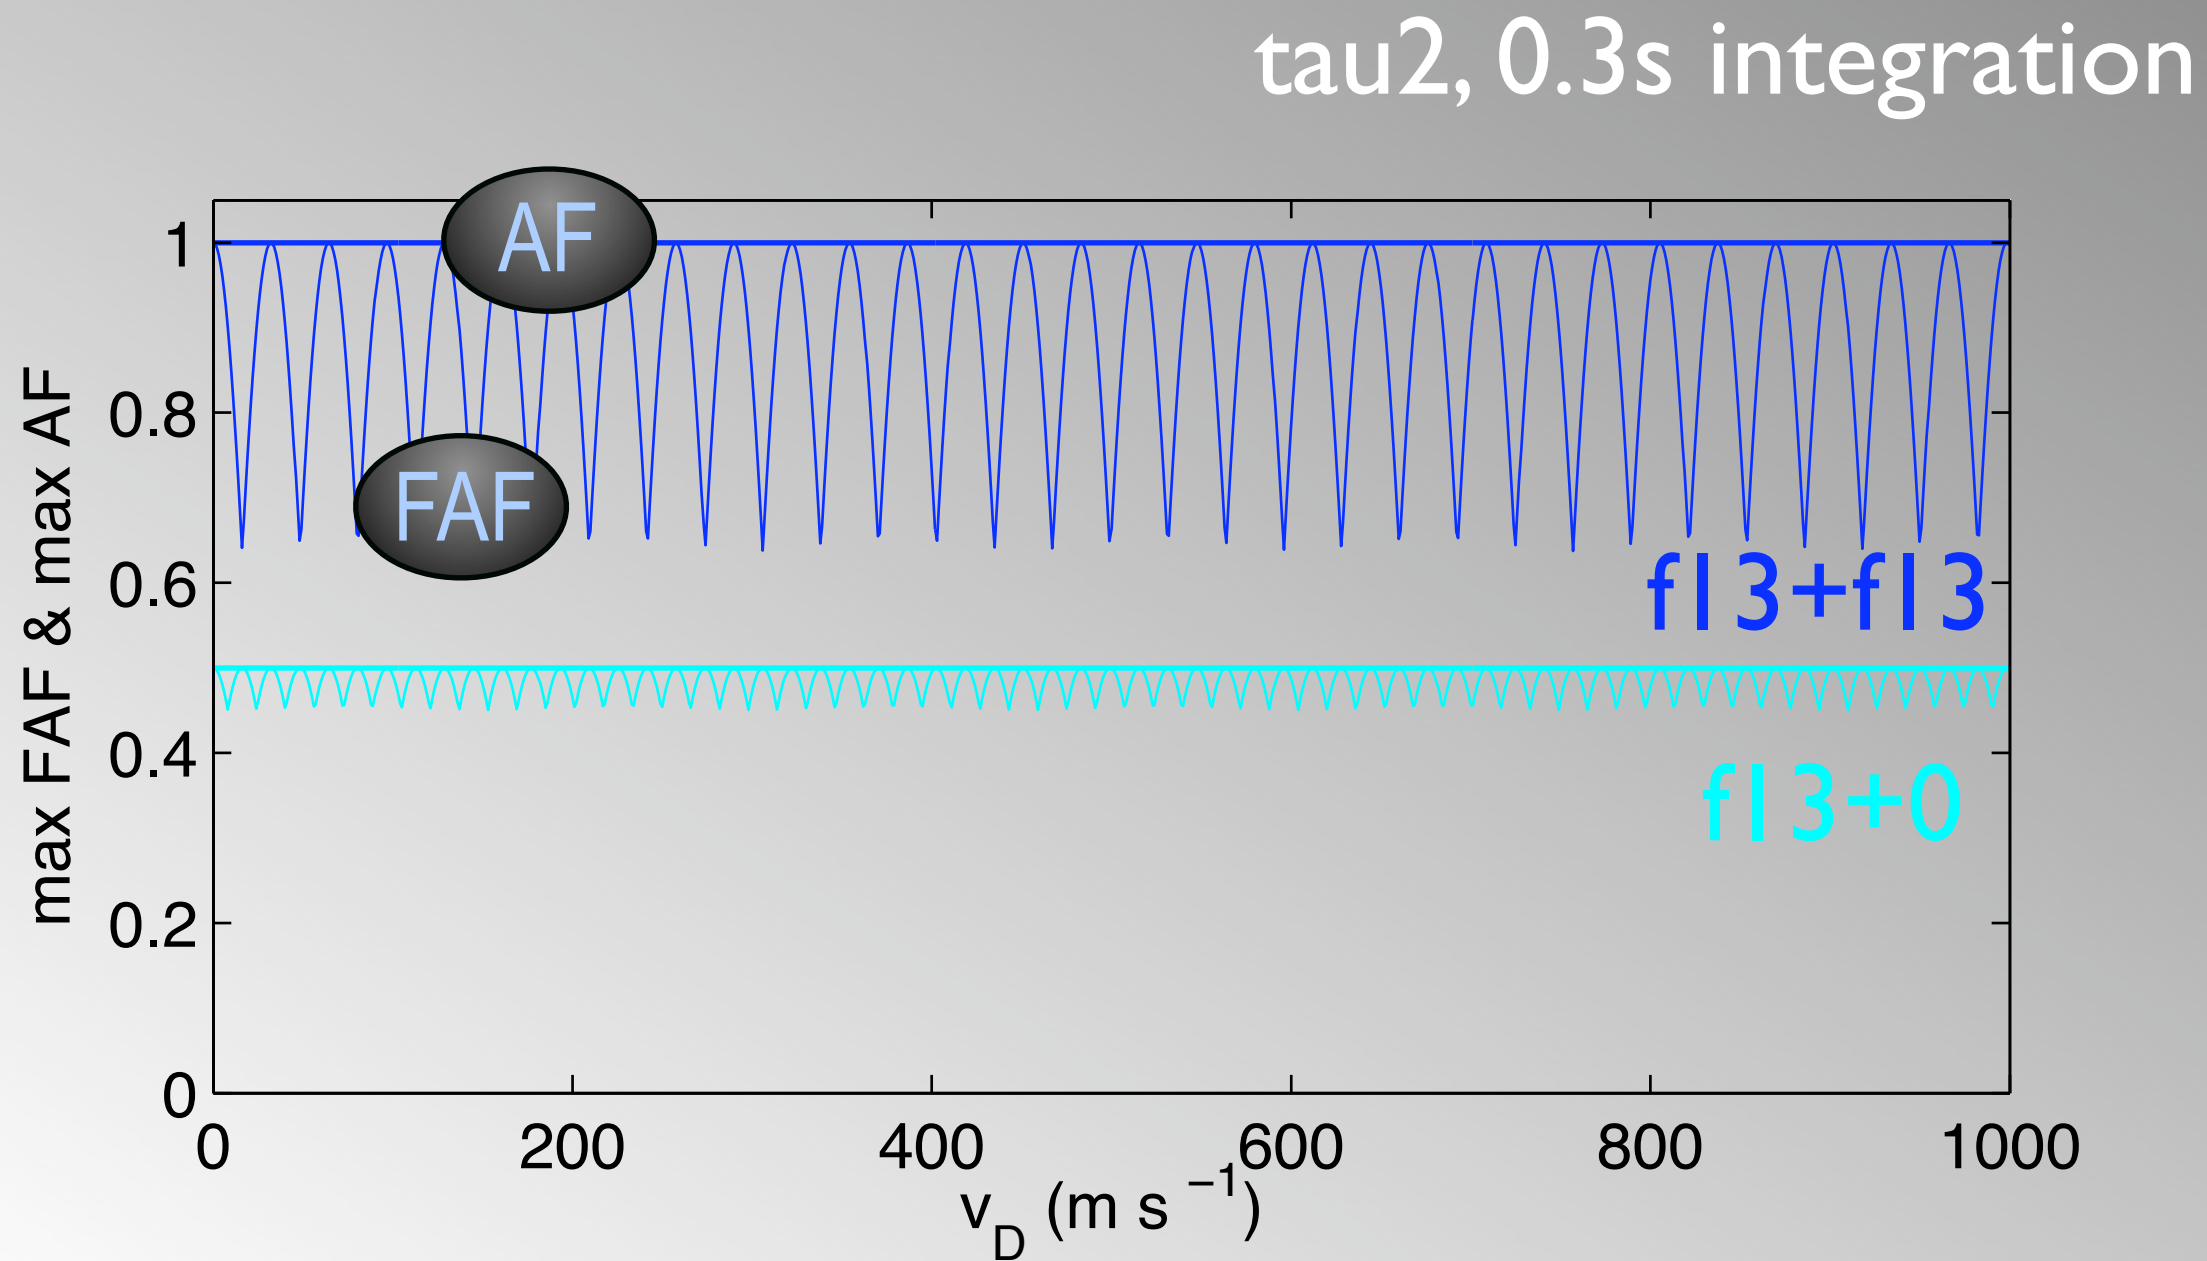

Effect of acceleration error

Effect of acceleration error

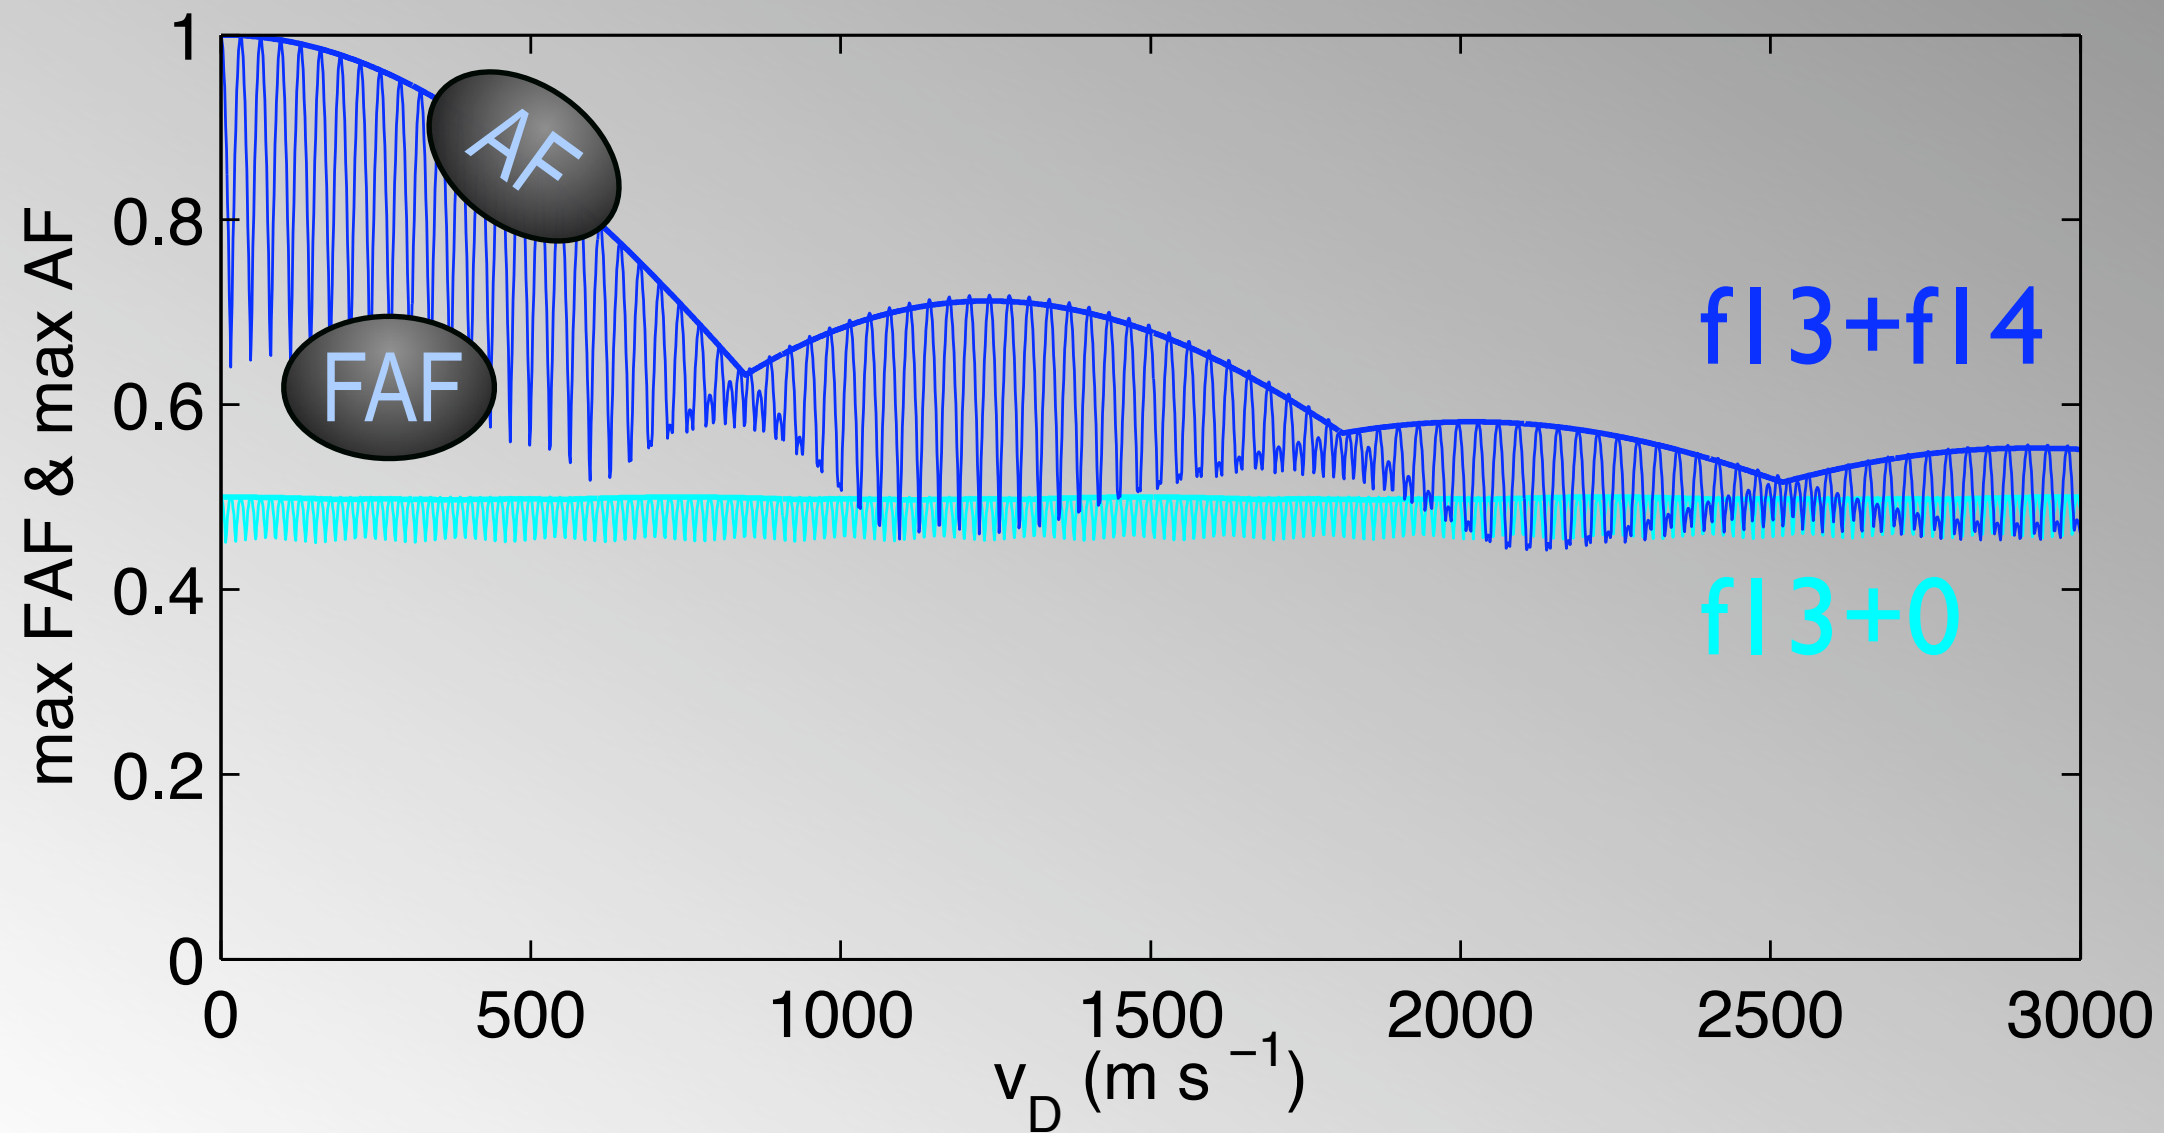

AF vs FAF, single freq. case

AF vs FAF, dual freq. case

Real-time small-size space debris detection with Eiscat
radar facilities

SUMMARY

At the moment ...

- Data collection and detection automated and RT.
- Event composing benefits of a manual step. To be included into foreseeable future.
- Analysis from events to parameters automated.
- Sensitivity as in the precursor study.
- Can handle long SD measurements in almost RT.
- SD system installed in Tromso. Ready to go.

In the future ...

- Made software more robust.
- A spare for HW exists, for now. But.
- Tackle remaining problems of the theory, including
 - What is the actual detection sensitivity?
 - How to make best use of 2-frequency data (coincidence-based detection?)
 - Can anything be done to mitigate τ^2 R-gap?
